

Automated Seed Quality Testing System

Seed Quality Testing

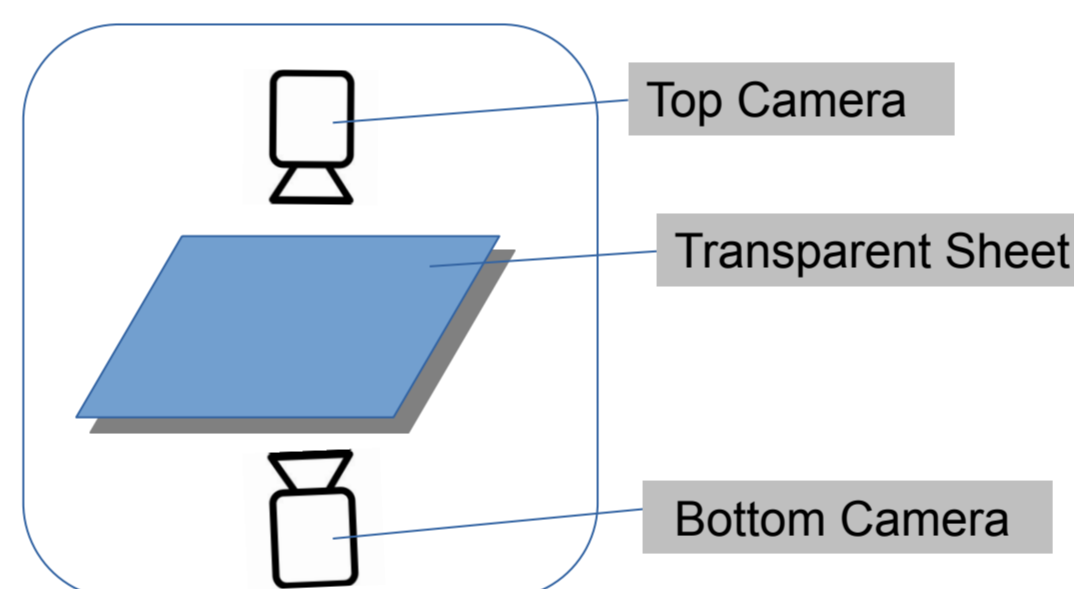

Data-set & Fake Image Generation

Image Acquisition
-Corn seed's images have been acquired in a controlled environment.

Top and Bottom View

Fake Images Generation
-Generate the fake images to balanced the data set and increase the diversity of the class instances.

- Image-to-Image Generation
- DCGAN, BigGAN
 - Conditional Image Generation
 - Image-to-Image Generation

Class Broken(Fake Image)

Labeling the images

Manually

- Seeds Classes:
1. Broken(B)
 2. Discolored(D)
 3. Pure(P)
 4. Silkcut(S)

Class	Real + Fake (Instances)
Broken	7267 + 2937
Discolored	5670 + 2938
Pure	3114 + 5823
Silkcut	1751 + 5823

Agriculture is the basic and the widest area for work and has a large number of diverse problem sets related which can be solved using the Computer Vision and the new state-of-the-art (ML models).

Manual inspections have many problems in maintaining consistency and ensuring a satisfactory detection efficiency.

Huge labor work.

Classification

Image Classification- Supervised Deep Learning,

Transfer Learning.

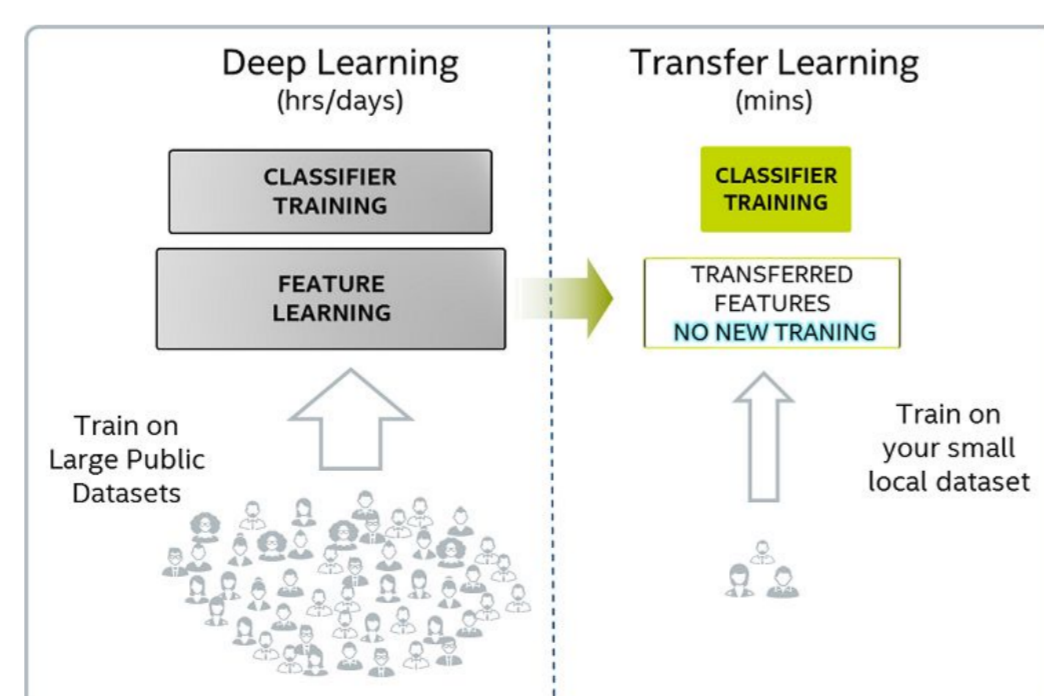

Resnet18, VGG16, GoogleNet, Mobilenet.

Fine-grained classification-challenging

due to the difficulty of finding discriminative

features.

Experiments & Results

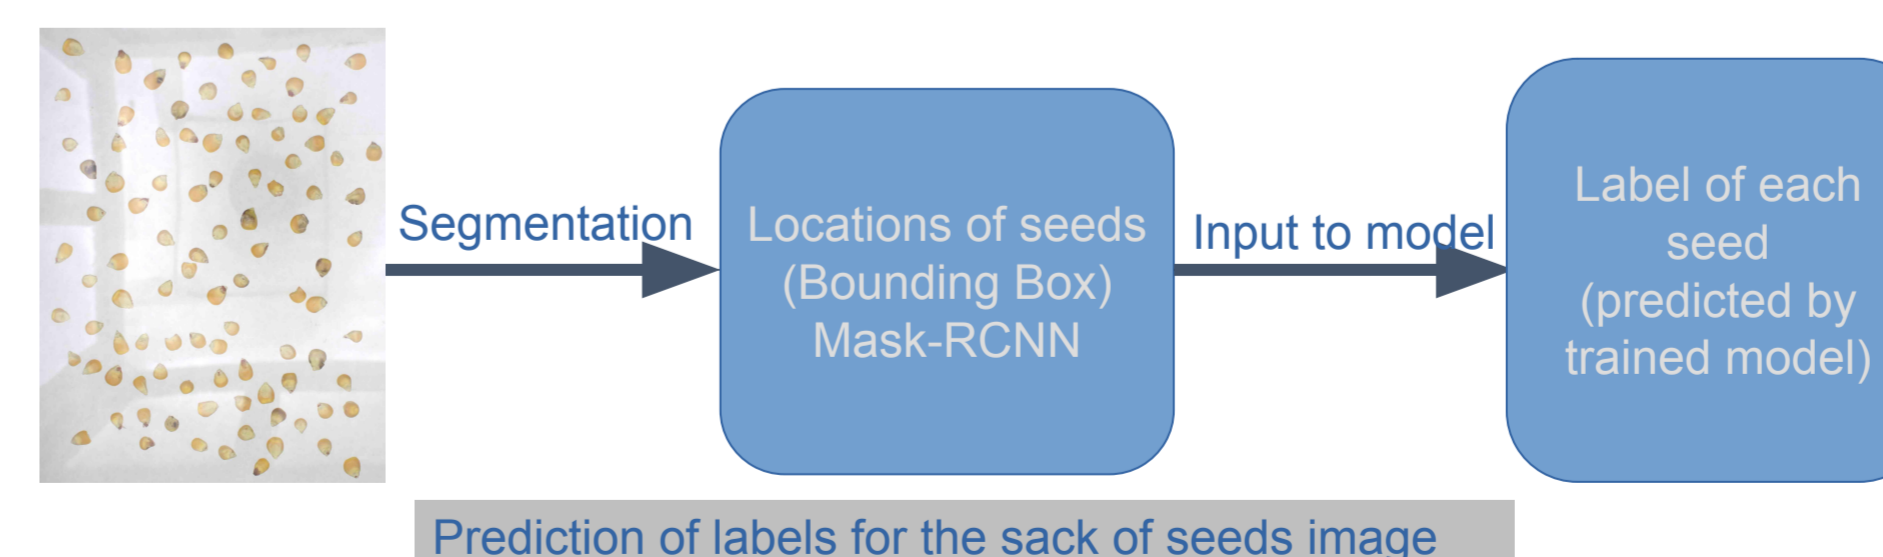

Accuracy

DNN	Before adding fake images	After adding fake images
resnet18	71.58 %	89.62 %

Confusion Matrix

There are some images in the dataset which may belong to more than one class and creates the confusion for the classifier

	Broken	Discolored	Pure	Silkcut
Broken	1418	69	154	41
Discolored	110	1619	81	20
Pure	89	51	1877	18
Silkcut	31	25	27	1477

Prediction of labels for the sack of seeds image

Application

- Provide suggestions and Insight to farmers.
- Agricultural Automation.
- Monitoring growth of crops.
- Classification and quality inspection of agricultural products.
